1 Introduction

In this manual, we will show how to use the methylKit package. methylKit is an R package for analysis and annotation of DNA methylation information obtained by high-throughput bisulfite sequencing. The package is designed to deal with sequencing data from RRBS and its variants. But it can potentially handle whole-genome bisulfite sequencing data if proper input format is provided.

1.1 DNA methylation

DNA methylation in vertebrates typically occurs at CpG dinucleotides, however non-CpG Cs are also methylated in certain tissues such as embryonic stem cells. DNA Methylation can act as an epigenetic control mechanism for gene regulation. Methylation can hinder binding of transcription factors and/or methylated bases can be bound by methyl-binding-domain proteins which can recruit chromatin remodeling factors. In both cases, the transcription of the regulated gene will be effected. In addition, aberrant DNA methylation patterns have been associated with many human malignancies and can be used in a predictive manner. In malignant tissues, DNA is either hypo-methylated or hyper-methylated compared to the normal tissue. The location of hyper- and hypo-methylated sites gives a distinct signature to many diseases. Traditionally, hypo-methylation is associated with gene transcription (if it is on a regulatory region such as promoters) and hyper-methylation is associated with gene repression.

1.2 High-throughput bisulfite sequencing

Bisulfite sequencing is a technique that can determine DNA methylation patterns. The major difference from regular sequencing experiments is that, in bisulfite sequencing DNA is treated with bisulfite which converts cytosine residues to uracil, but leaves 5-methylcytosine residues unaffected. By sequencing and aligning those converted DNA fragments it is possible to call methylation status of a base. Usually, the methylation status of a base determined by a high-throughput bisulfite sequencing will not be a binary score, but it will be a percentage. The percentage simply determines how many of the bases that are aligning to a given cytosine location in the genome have actual C bases in the reads. Since bisulfite treatment leaves methylated Cs intact, that percentage will give us percent methylation score on that base. The reasons why we will not get a binary response are 1) the probable sequencing errors in high-throughput sequencing experiments 2) incomplete bisulfite conversion 3) (and a more likely scenario) is heterogeneity of samples and heterogeneity of paired chromosomes from the same sample

2 Basics

2.1 Reading the methylation call files

We start by reading in the methylation call data from bisulfite sequencing with read function. Reading in the data this way will return a methylRawList object which stores methylation information per sample for each covered base. The methylation call files are basically text files that contain percent methylation score per base. A typical methylation call file looks like this:

```
base strand coverage freqC
        chrBase
                  chr
                                                       freqT
1 chr21.9764539 chr21 9764539
                                            12 25.00
                                                       75.00
2 chr21.9764513 chr21 9764513
                                    R
                                                0.00 100.00
3 chr21.9820622 chr21 9820622
                                    F
                                                0.00 100.00
4 chr21.9837545 chr21 9837545
                                    F
                                            11
                                                0.00 100.00
5 chr21.9849022 chr21 9849022
                                    F
                                           124 72.58 27.42
```

Most of the time bisulfite sequencing experiments have test and control samples. The test samples can be from a disease tissue while the control samples can be from a healthy tissue. You can read a set of methylation call files that have test/control conditions giving treatment vector option. For sake of subsequent analysis, file.list, sample.id and treatment option should have the same order. In the following example, first two files are have the sample ids "test1" and "test2" and as determined by treatment vector they belong to the same group. The third and fourth files have sample ids "ctrl1" and "ctrl2" and they belong to the same group as indicated by the treatment vector.

2.2 Reading the methylation calls from sorted Bismark alignments

Alternatively, methylation percentage calls can be calculated from sorted SAM file(s) from Bismark aligner and read-in to the memory. Bismark is a popular aligner for bisulfite sequencing reads [1]. read.bismark function is designed to read-in Bismark SAM files as methylRaw or methylRawList objects which store per base methylation calls. SAM files must be sorted by chromosome and read position columns, using 'sort' command in unix-like machines will accomplish such a sort easily.

The following command reads a sorted SAM file and creates a methylRaw object for CpG methylation. The user has the option to save the methylation call files to a folder given by save.folder option. The saved files can be read-in using the read function when needed.

```
> my.methRaw=read.bismark(
+ location=system.file("extdata", "test.fastq_bismark.sorted.min.sam",
+ package = "methylKit"),
+ sample.id="test1",assembly="hg18",read.context="CpG",save.folder=getwd())
```

It is also possible to read multiple SAM files at the same time, check ${\tt read.bismark}$ documentation.

2.3 Descriptive statistics on samples

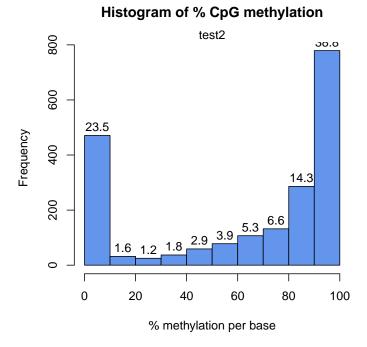

Since we read the methylation data now, we can check the basic stats about the methylation data such as coverage and percent methylation. We now have a methylatiot object which contains methylation information per sample. The following command prints out percent methylation statistics for second sample: "test2"

```
> getMethylationStats(myobj[[2]],plot=F,both.strands=F)
methylation statistics per base
summary:
   Min. 1st Qu. Median Mean 3rd Qu. Max.
   0.00 20.00 82.79 63.17 94.74 100.00
```

percentiles: 30% 0% 10% 20% 40% 50% 60% 70% 0.00000 0.00000 0.00000 48.38710 70.00000 82.78556 90.00000 93.33333 80% 90% 95% 99% 99.5% 99.9% 100% 96.42857 100.00000 100.00000 100.00000 100.00000 100.00000 100.00000

The following command plots the histogram for percent methylation distribution. The figure below is the histogram and numbers on bars denote what percentage of locations are contained in that bin. Typically, percent methylation histogram should have two peaks on both ends. In any given cell, any given base are either methylated or not. Therefore, looking at many cells should yield a similar pattern where we see lots of locations with high methylation and lots of locations with low methylation.

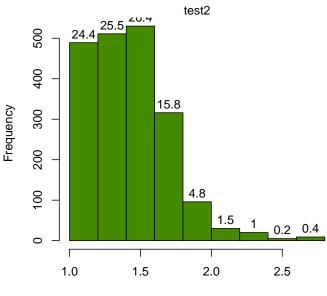

> getMethylationStats(myobj[[2]],plot=T,both.strands=F)

We can also plot the read coverage per base information in a similar way, again numbers on bars denote what percentage of locations are contained in that bin. Experiments that are highly suffering from PCR duplication bias will have a secondary peak towards the right hand side of the histogram.

- > library ("graphics")
- > getCoverageStats(myobj[[2]],plot=T,both.strands=F)

Histogram of CpG coverage

log10 of read coverage per base

2.4 Filtering samples based on read coverage

It might be useful to filter samples based on coverage. Particularly, if our samples are suffering from PCR bias it would be useful to discard bases with very high read coverage. Furthermore, we would also like to discard bases that have low read coverage, a high enough read coverage will increase the power of the statistical tests. The code below filters a methylRawList and discards bases that have coverage below 10X and also discards the bases that have more than 99.9th percentile of coverage in each sample.

3 Comparative analysis

3.1 Merging samples

In order to do further analysis, we will need to get the bases covered in all samples. The following function will merge all samples to one object for base-pair locations that are covered in all samples. Setting destrand=TRUE (the default is FALSE) will merge reads on both strands of a CpG dinucleotide. This provides better coverage, but only advised when looking at CpG methylation

(for CpH methylation this will cause wrong results in subsequent analyses). In addition, setting destrand=TRUE will only work when operating on base-pair resolution, otherwise setting this option TRUE will have no effect. The unite() function will return a methylBase object which will be our main object for all comparative analysis. The methylBase object contains methylation information for regions/bases that are covered in all samples.

> meth=unite(myobj, destrand=FALSE)

Let us take a look at the data content of methylBase object:

> head(meth)

methylBase object with 6 rows

 -	_	_	_	_	_	_	_	_	_	_	_	

	id	chr	start	en	.d s	trand	coverage1	numCs1	numTs1

sample.ids: test1 test2 ctrl1 ctrl2

destranded FALSE assembly: hg18 context: CpG treament: 1 1 0 0 resolution: base

By default, unite function produces bases/regions covered in all samples. That requirement can be relaxed using "min.per.group" option in unite function.

- > # creates a methylBase object. Only CpGs covered at least in 1 sample per group will be re> # there were two groups defined by the treatment vector given during the creation of myob
- > meth.min=unite(myobj,min.per.group=1L)

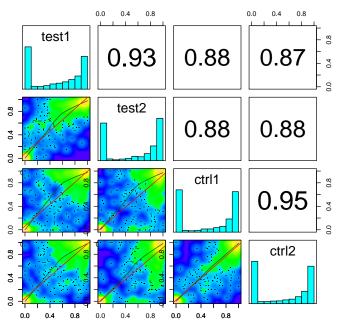

3.2 Sample Correlation

We can check the correlation between samples using getCorrelation. This function will either plot scatter plot and correlation coefficients or just print a correlation matrix

> getCorrelation(meth,plot=T)

```
test1 test2 ctrl1 ctrl2
test1 1.0000000 0.9252530 0.8767865 0.8737509
test2 0.9252530 1.0000000 0.8791864 0.8801669
ctrl1 0.8767865 0.8791864 1.0000000 0.9465369
ctrl2 0.8737509 0.8801669 0.9465369 1.0000000
```

CpG base pearson cor.

3.3 Clustering samples

We can cluster the samples based on the similarity of their methylation profiles. The following function will cluster the samples and draw a dendrogram.

> clusterSamples(meth, dist="correlation", method="ward", plot=TRUE)

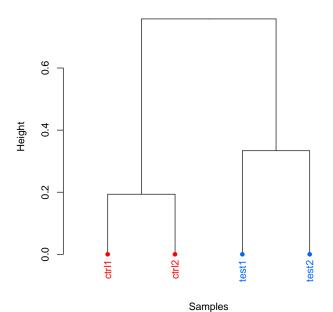

Call:

hclust(d = d, method = HCLUST.METHODS[hclust.method])

Cluster method : ward
Distance : pearson

Number of objects: 4

CpG methylation clustering

Distance method: "correlation"; Clustering method: "ward"

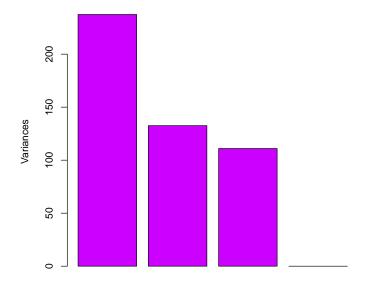

Setting the plot=FALSE will return a dendrogram object which can be manipulated by users or fed in to other user functions that can work with dendrograms.

> hc = clusterSamples(meth, dist="correlation", method="ward", plot=FALSE)

We can also do a PCA analysis on our samples. The following function will plot a scree plot for importance of components.

> PCASamples(meth, screeplot=TRUE)

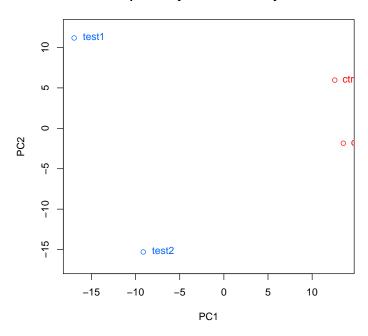

We can also plot PC1 and PC2 axis and a scatter plot of our samples on those axis which will reveal how they cluster.

> PCASamples(meth)

CpG methylation PCA Analysis

3.4 Tiling windows analysis

For some situations, it might be desirable to summarize methylation information over tiling windows rather than doing base-pair resolution analysis. methylKit provides functionality to do such analysis. The function below tiles the genome with windows 1000bp length and 1000bp step-size and summarizes the methylation information on those tiles. In this case, it returns a methylRawList object which can be fed into unite and calculateDiffMeth functions consecutively to get differentially methylated regions. The tilling function adds up C and T counts from each covered cytosine and returns a total C and T count for each tile

```
> tiles=tileMethylCounts(myobj,win.size=1000,step.size=1000)
> head(tiles[[1]],3)
```

methylRaw object with 3 rows

	id	chr	start	end	strand	coverage	${\tt numCs}$	${\tt numTs}$
1	chr21.9764001.9765000	chr21	9764001	9765000	*	24	3	21
2	chr21.9820001.9821000	chr21	9820001	9821000	*	13	0	13
3	chr21.9837001.9838000	chr21	9837001	9838000	*	11	0	11

sample.id: test1
assembly: hg18
context: CpG
resolution: region

3.5 Finding differentially methylated bases or regions

calculateDiffMeth() function is the main function to calculate differential methylation. Depending on the sample size per each set it will either use Fisher's exact or logistic regression to calculate P-values. P-values will be adjusted to Q-values using SLIM method [2].

> myDiff=calculateDiffMeth(meth)

After q-value calculation, we can select the differentially methylated regions/bases based on q-value and percent methylation difference cutoffs. Following bit selects the bases that have q-value<0.01 and percent methylation difference larger than 25%. If you specify type="hyper" or type="hypo" options, you will get hyper-methylated or hypo-methylated regions/bases.

```
> # get hyper methylated bases
> myDiff25p.hyper=get.methylDiff(myDiff,difference=25,qvalue=0.01,type="hyper")
> #
> # get hypo methylated bases
> myDiff25p.hypo=get.methylDiff(myDiff,difference=25,qvalue=0.01,type="hypo")
> #
> #
> # get all differentially methylated bases
> myDiff25p=get.methylDiff(myDiff,difference=25,qvalue=0.01)
```

We can also visualize the distribution of hypo/hyper-methylated bases/regions per chromosome using the following function. In this case, the example set includes only one chromosome. The list shows percentages of hypo/hyper methylated bases over all the covered bases in a given chromosome.

```
> diffMethPerChr(myDiff,plot=FALSE,qvalue.cutoff=0.01, meth.cutoff=25)
```

3.5.1 Finding differentially methylated bases using multiple-cores

The differential methylation calculation speed can be increased substantially by utilizing multiple-cores in a machine if available. Both Fisher's Exact test and logistic regression based test are able to use multiple-core option.

The following piece of code will run differential methylation calculation using 2 cores.

> myDiff=calculateDiffMeth(meth,num.cores=2)

4 Annotating differentially methylated bases or regions

We can annotate our differentially methylated regions/bases based on gene annotation. In this example, we read the gene annotation from a bed file and annotate our differentially methylated regions with that information. This will tell us what percentage of our differentially methylated regions are on promoters/introns/exons/intergenic region. Similar gene annotation can be fetched using GenomicFeatures package available from Bioconductor.org.

```
> gene.obj=read.transcript.features(system.file("extdata", "refseq.hg18.bed.txt",
                                             package = "methylKit"))
> #
> # annotate differentially methylated Cs with promoter/exon/intron using annotation data
> annotate.WithGenicParts(myDiff25p,gene.obj)
summary of target set annotation with genic parts
133 rows in target set
_____
percentage of target features overlapping with annotation :
                         intron intergenic
                exon
  27.81955
           15.03759
                       34.58647
                                  57.14286
percentage of target features overlapping with annotation (with promoter>exon>intron precede

                          intron intergenic
                 exon
  27.81955
              0.00000
                        15.03759
                                   57.14286
percentage of annotation boundaries with feature overlap :
  promoter
                 exon
                         intron
```

0.28604119 0.02683483 0.17068273

```
summary of distances to the nearest TSS: Min. 1st Qu. Median Mean 3rd Qu. Max. 5 828 45160 52030 94640 313500
```

Similarly, we can read the CpG island annotation and annotate our differentially methylated bases/regions with them.

4.1 Regional analysis

We can also summarize methylation information over a set of defined regions such as promoters or CpG islands. The function below summarizes the methylation information over a given set of promoter regions and outputs a methylRaw or methylRawList object depending on the input.

```
> promoters=regionCounts(myobj,gene.obj$promoters)
> head(promoters[[1]])
methylRaw object with 6 rows
```

```

sample.id: test1
assembly: hg18
context: CpG
resolution: region

4.2 Convenience functions for annotation objects

After getting the annotation of differentially methylated regions, we can get the distance to TSS and nearest gene name using the getAssociationWithTSS function.

- > diffAnn=annotate.WithGenicParts(myDiff25p,gene.obj)
- > # target.row is the row number in myDiff25p
- > head(getAssociationWithTSS(diffAnn))

target.row dist.to.feature feature.name feature.strand 60 NM_199260 1 951 2 60.1 931 NM_199260 60.2 3 838 NM_199260 NM_199260 60.3 4 828 60.4 5 802 NM_199260 723 NM_199260 60.5

It is also desirable to get percentage/number of differentially methylated regions that overlap with intron/exon/promoters

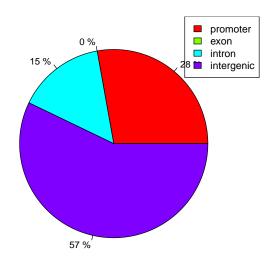

> getTargetAnnotationStats(diffAnn,percentage=TRUE,precedence=TRUE)

```
promoter exon intron intergenic 27.81955 0.00000 15.03759 57.14286
```

We can also plot the percentage of differentially methylated bases overlapping with exon/intron/promoters $\,$

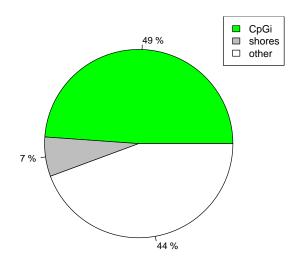

- > plotTargetAnnotation(diffAnn,precedence=TRUE,
- + main="differential methylation annotation")

differential methylation annotation

We can also plot the CpG island annotation the same way. The plot below shows what percentage of differentially methylated bases are on CpG islands, CpG island shores and other regions.

differential methylation annotation

It might be also useful to get percentage of intron/exon/promoters that overlap with differentially methylated bases.

> getFeatsWithTargetsStats(diffAnn,percentage=TRUE)

promoter exon intron 0.28604119 0.02683483 0.17068273

5 methylKit convenience functions

5.1 coercion

Most methylKit objects (methylRaw,methylBase and methylDiff) can be coerced to GRanges objects from GenomicRanges package. Coercing methylKit objects to GRanges will give users additional flexiblity when customising their analyses.

```
> class(meth)
```

[1] "methylBase"
attr(,"package")
[1] "methylKit"

> as(meth, "GRanges")

5.2 select

We can also select rows from methylRaw, methylBase and methylDiff objects with "select" function. An appropriate methylKit object will be returned as a result of "select" function.

> select(meth,1:10) # select first 10 rows of a methylBase object

```
methylBase object with 10 rows
```

```

5.3 reorganize

methylBase and methylRawList can be reorganized by reorganize function. The function can subset the objects based on provided sample ids, it also creates a new treatment vector determining which samples belong to which group. Order of sample ids should match the treatment vector order.

```
> # creates a new methylRawList object
> myobj2=reorganize(myobj,sample.ids=c("test1","ctrl2"),treatment=c(1,0) )
> # creates a new methylBase object
> meth2 =reorganize(meth,sample.ids=c("test1","ctrl2"),treatment=c(1,0) )
```

5.4 percMethylation

Percent methylation values can be extracted from methylBase object by using percMethylation function.

```
> # creates a matrix containing percent methylation values
> perc.meth=percMethylation(meth)
```

6 Frequently Asked Questions

Detailed answers to some of the frequently asked questions and various how-tos can be found at http://zvfak.blogspot.com/search/label/methylKit. In addition, http://code.google.com/p/methylkit/ has online documentation and links to tutorials and other related material. Apart from those here are some of the frequently asked questions.

6.1 How can I select certain regions/bases from methylRaw or methylBase objects?

```
see ?select or help("[", package = "methylKit")
```

6.2 How can I find if my regions of interest overlap with exon/intron/promoter/CpG island etc.?

Currently, we will be able to tell you if your regions/bases overlap with the genomic features or not. see ?getMembers.

6.3 How can I find the nearest TSS associated with my ${ m CpGs}$

see ?getAssociationWithTSS

6.4 How do you define promoters and CpG island shores

Promoters are defined by options at read.transcript.features function. The default option is to take -1000,+1000bp around the TSS and you can change that. Same goes for CpG islands when reading them in via read.feature.flank function. Default is to take 2000bp flanking regions on each side of the CpG island as shores. But you can change that as well.

6.5 What is Bismark SAM output look like, where can I get more info?

Check the Bismark [1] website and there are also example files that ship with the package. Look at their formats and try to run different variations of read.bismark() command on example files.

6.6 How can I reorder or remove samples at/from methyl-RawList or methylBase objects?

see ?reorganize

6.7 Should I normalize my data?

methylKit comes with a simple normalizeCoverage() function to normalize read coverage distributions between samples. Ideally, you should first filter bases with extreme coverage to account for PCR bias using filterByCoverage() function, then run normalizeCoverage() function to normalize coverages between samples. These two functions will help reduce the bias in the statistical tests that might occur due to systematic over-sampling of reads in certain samples.

6.8 How can I force methylKit to use Fisher's exact test?

methylKit decides which test to use based on number of samples per group. In order to use Fisher's exact there must be one sample in each of the test and control groups. So if you have multiple samples for group, the package will employ Logistic Regression based test. However, you can use pool() function to pool samples in each group so that you have one representative sample per group. pool() function will sum up number of Cs and Ts in each group. We recommend using filterByCoverage() and normalizeCoverage() functions prior to using pool(). see ?pool

6.9 Can use data from other aligners than Bismark in methylKit?

Yes, you can. methylKit can read any generic methylation percentage/ratio file as long as that text file contains columns for chrosome, start, end, strand,

coverage and number of methylated cytosines. However, methylKit can only process SAM files from Bismark. For other aligners, you need to get a text file containing the minimal information described above. Some aligners will come with scripts or built-in tools to provide such files. See http://zvfak.blogspot.com/2012/10/how-to-read-bsmap-methylation-ratio.html for how to read methylation ratio files from BSMAP [3] aligner.

7 Acknowledgements

This package is developed at Weill Cornell Medical College by Altuna Akalin with important code contributions from Sheng Li and Matthias Kormaksson. We wish to thank especially Maria E. Figueroa, Francine Garret-Bakelman, Chrisopher Mason and Ari Melnick for their contribution of ideas, data and support. Their support and discussions lead to development of methylKit.
